AN ATLAS OF OBLIQUE-INCIDENCE  
IONOGRAMS

BY VAUGHN AGY, KENNETH DAVIES  
AND ROGER SALAMAN

---

U. S. DEPARTMENT OF COMMERCE  
NATIONAL BUREAU OF STANDARDS

## THE NATIONAL BUREAU OF STANDARDS

### Functions and Activities

The functions of the National Bureau of Standards are set forth in the Act of Congress, March 3, 1901, as amended by Congress in Public Law 619, 1950. These include the development and maintenance of the national standards of measurement and the provision of means and methods for making measurements consistent with these standards; the determination of physical constants and properties of materials; the development of methods and instruments for testing materials, devices, and structures; advisory services to government agencies on scientific and technical problems; invention and development of devices to serve special needs of the Government; and the development of standard practices, codes, and specifications. The work includes basic and applied research, development, engineering, instrumentation, testing, evaluation, calibration services, and various consultation and information services. Research projects are also performed for other government agencies when the work relates to and supplements the basic program of the Bureau or when the Bureau's unique competence is required. The scope of activities is suggested by the listing of divisions and sections on the inside of the back cover.

### Publications

The results of the Bureau's work take the form of either actual equipment and devices or published papers. These papers appear either in the Bureau's own series of publications or in the journals of professional and scientific societies. The Bureau itself publishes three periodicals available from the Government Printing Office: The Journal of Research, published in four separate sections, presents complete scientific and technical papers; the Technical News Bulletin presents summary and preliminary reports on work in progress; and Basic Radio Propagation Predictions provide data for determining the best frequencies to use for radio communications throughout the world. There are also five series of nonperiodical publications: Monographs, Applied Mathematics Series, Handbooks, Miscellaneous Publications, and Technical Notes.

Information on the Bureau's publications can be found in NBS Circular 460, Publications of the National Bureau of Standards (\$1.25) and its Supplement (\$1.50), available from the Superintendent of Documents, Government Printing Office, Washington 25, D.C.

AN ATLAS OF OBLIQUE-INCIDENCE IONOGRAMS

by

Vaughn Agy, Kenneth Davies  
and Roger Salaman

NBS Technical Notes are designed to supplement the Bureau's regular publications program. They provide a means for making available scientific data that are of transient or limited interest. Technical Notes may be listed or referred to in the open literature. They are for sale by the Office of Technical Services, U. S. Department of Commerce, Washington 25, D. C.

# AN ATLAS OF OBLIQUE-INCIDENCE IONOGRAMS

by

Vaughn Agy, Kenneth Davies  
and Roger Salaman

## INTRODUCTION

This atlas is intended to serve a twofold purpose: first, to provide a compilation of records, of a type becoming standard in the field of ionospheric research, for those workers who are not now familiar with them, and second, to present records which are characteristic of the specific paths used by the National Bureau of Standards for consideration by those using other paths.

To date, NBS sweep-frequency experiments have been carried out over two approximately east-west paths: Sterling, Va. - St. Louis, Mo. (about 1150 km), and Sterling, Va. - Boulder, Colo. (about 2370 km). The experimental data on these paths were taken under the supervision of R. Silberstein and P. G. Sulzer. For each path a midpoint vertical-incidence station was established within about one mile of the geographical midpoint of the great circle path. For the Sterling - St. Louis path the midpoint station was near Batavia, Ohio and for the Sterling - Boulder path it was near Carthage, Illinois. The shorter path was used from August 1951 to December 1952 when the St. Louis equipment was moved west to Boulder. From September 1953 to May 1955, routine records were made over the Sterling-Boulder path, after which time various minor equipment changes were made to improve the time-delay records and to obtain records giving more propagation information for the path.

The data concerning the end-point stations are tabulated below:

<u>Equipment</u>	<u>Power</u>	<u>Time</u>	<u>Sweep Frequency</u>	<u>Pulse Length</u>	<u>Pulse Rep Rate</u>	<u>Antennas</u>
C-3 (modified)	10 kw	12 min*	2-25 Mc	50 $\mu$ s**	25/sec	Horizontal Rhombic

\*Changed in 1955 to  $7\frac{1}{2}$  minutes.

\*\*Unless otherwise noted in the body of the atlas.

For the Sterling-St. Louis path the time at which each record was made (indicated below and to the left of each record shown) is 75° West Meridian Time. For the Sterling-Boulder path, 90° West Meridian Time was used. The time given for each oblique-incidence ionogram is that at which the frequency passed upward through 23 Mc (changed to 24 Mc during the first months of 1958).

The relatively slow sweep time allowed for manual adjustment, when necessary, to synchronize the two equipments. The midpoint vertical-incidence equipment operated in normal fashion, sweeping from 1 Mc to 25 Mc in 15 seconds once every 6 minutes and later once every 3 minutes. The 3 minute spacing between sweeps allowed selection of the vertical-incidence ionogram made within  $1\frac{1}{2}$  minutes of the time the slower oblique-incidence sweep passed through the frequency of interest, e.g., the MUF.

The oblique-incidence ionograms are plots of time-delay against frequency (on a linear scale). The ordinate (time-delay) scale, however, just as for vertical-incidence ionograms, is calibrated in terms of the apparent virtual half-path. In order to determine the absolute time delay (or virtual half-path) between the two stations at a given frequency, it is necessary to take the arithmetic mean of the ordinates on the two end-point records. For given virtual heights\* of reflection, the virtual half-paths are plotted in Figure 1 for the Sterling-St. Louis path and in Figure 2 for the Sterling-Boulder path. In addition to the 1-, 2-, 3-hop modes, the M and N modes are presented involving both F-layer reflections and E-layer reflections (with the E-layer virtual height assumed to be 100 km).

The ionograms for the shorter path usually show vertical-incidence as well as oblique-incidence traces; for the longer path, however, in order to avoid undue compression of the virtual half-path scale, the first 1000 km of half-path are not recorded. On some of the later records, one or both scales are expanded in order to allow examination of some of the detailed structure of the recorded traces.

In some cases (e.g. Section I-3) the midpoint vertical-incidence records are included for comparison. Although not always labeled, these records are easily identified by the logarithmic frequency scale. The end-point records, unless otherwise noted, were those made at the western terminus of the path, i.e. St. Louis for the shorter path and Boulder for the longer path. The primary reason for this choice is the fact that these records usually are freer of interference than those made at Sterling.

---

\*Virtual height in this sense, for the 1-hop mode, is the height above a spherical earth of the apex of an isosceles triangle whose base is the chord between the two stations and whose legs are equal in length to the absolute virtual half-path between the stations.

FIGURE 1

FIGURE 2

The body of the atlas is divided into three parts, giving examples of records made: (1) over the Sterling-St. Louis (1150 km) path, (2) over the Sterling-Boulder (2370 km) path during the routine phase of this part of the experiment, and (3) over the Sterling-Boulder path during the more recent phase of the experiment in which equipment changes were made to increase the observable detail in the ionograms and to make measurements of recorded pulse amplitudes. Some sequences of ionograms are included to show the variations during a day, or during shorter periods when the development of a specific phenomenon can be seen. Other single records are included simply to show the occurrence rather than the development of a particular phenomenon. Many of the records for which interpretations are not readily evident are included because of the interest they may arouse. However, it is not the purpose of the atlas to give detailed interpretations of the ionograms shown.

For the most part, the analysis of the records has consisted of a comparison of the MUF determined directly from the oblique-incidence records with that obtained by applying the appropriate Smith transmission curves (see references) to the midpoint vertical-incidence ionograms. It is worth noting that although, on the average, the scaling of MUF from the vertical-incidence midpoint records agrees well with the observed MUF, there are frequent discrepancies in detail. For an eventual understanding of oblique-incidence propagation, the discrepancies are just as important as the cases of close agreement.

The use of various descriptive terms has developed to aid in the description of certain aspects of the oblique-incidence ionograms. One of these terms is "nose", which is suggested by the shape of the trace on an oblique-incidence ionogram indicating the merging of a high-angle and a low-angle ray. It has become customary occasionally to speak of the "junction frequency" or simply the "nose frequency" for a particular layer when referring to the classical MUF for that layer, but when complications arise, as shown in Sections II-3 and III-3, "nose" may also be used to refer to a junction frequency different from the MUF.

Ionograms Showing Spread Echo

May 1, 1952

The midpoint vertical-incidence record is not only spread but weak, indicating high absorption. The oblique-incidence record is somewhat spread but appears to be relatively strong.

---

May 29, 1952

On these records spread echoes are evident at vertical incidence but the oblique-incidence traces are relatively sharp.

---

May 29, 1952

Moderate spread on the oblique-incidence records accompanies severe spread seen at vertical incidence.

---

The great amount of spread apparent on the midpoint vertical-incidence ionograms represents a complicated ionospheric structure which shows itself in the complex traces seen on the oblique-incidence ionograms.

---

July 25, October 21, 1952

The July 25 ionograms show more spread at oblique incidence than at vertical incidence; the October 21 records show comparable spread.

Ionograms Showing MUF Extensions

September 11, 1952; October 3, September 3, 1951; September 12,  
July 18, September 26, 1952

Note the following:

- (1) The echoes at frequencies above that which the high-angle and low-angle rays merge. This has been named the MUF extension.
- (2) On July 18, September 12 and September 26, it is difficult to separate the 2-hop E echo from the 1-hop F1 echo.
- (3) On September 26 there is no extension on the F2 trace, perhaps because of the presence of the underlying F1 layer.
- (4) The presence of the MUF extension does not appear to be correlated with the presence of sporadic E.

Ionograms Showing Relative Importance of High-Angle Ray

May 14, 1952

The one-hop low-angle ray is cut off by sporadic E which is evident on the oblique-incidence record (1945) but not on the vertical-incidence ionogram (1942). The high-angle ray may, therefore, be relatively important (note the presence of M and N-type echoes).

---

May 15, 1952

Here again the low-angle ray has been cut off by intense sporadic E.

---

October 3, November 18, December 2, 1952

The high-angle ray here is relatively unimportant. This is especially typical of winter day conditions.

---

February 13, July 17, August 28, September 11, 1952

June 19, 1958

Sequence showing development of "outer" nose on oblique-incidence ionograms and blanketing by Es on end-point vertical-incidence ionograms.

\*Occasionally, as shown in the following records, in addition to the well defined "nose" representing the classical F2 MUF, a second nose appears at frequencies below (or above) the classical MUF. The additional nose, for the sake of brevity, is referred to as an "inner" (or "outer") nose.

## Equipment Effects

The June 24, 1958, 0659 and 0707 CST ionograms were received using 100 and 20  $\mu$ s transmitted pulses respectively. The June 26, 1958, 1944 CST ionogram was received with every 10th transmitter pulse changed to 100 or 20  $\mu$ s. The loss of detail with the longer pulse can be seen.

The top records on August 1, 1958 are those ordinarily received. The bottom records were taken simultaneously with large differentiation in the receiving system.

The 1323 CST ionogram of July 23, 1957 illustrates the effect of transmitter double pulsing. The parallel traces on the March 12, 1957 and April 23, 1957 ionograms may also be attributed to a deformed transmitter pulse.

Fixed Frequency vs. Sweep Frequency

May 7, 1958

The first ionogram shows the pulse received on 20.084 Mc, from 1920 to 2100 CST. The following sweep-frequency ionograms were obtained during the same period. Both transmitters used a 25  $\mu$ s pulse at a 25 pps repetition rate. The output of the fixed-frequency transmitter was about 200 kw.

The hesitation of the F2 MUF at about 20 Mc appears as a nose extension on the fixed-frequency record.

Sterling-Boulder  
(Experimental)A Sequence of A-scan Records Showing Field Strength  
Variations Near the MUF

In addition to the time-delay studies, some attention has been given to received field strengths. Here is shown a series of A-scan records made at Boulder and the corresponding oblique-incidence ionograms. The frequency at which the A-scan records were made increases upward in each column and from left to right. These were made at the rate of  $2\frac{1}{2}$  per second (or every .025 Mc). On each record, time delay increases toward the right. The pulse amplitudes — the scale is approximately linear — vary somewhat due to normal fading.

At frequencies greater than 14.8 Mc (near the top of the first column) the Pedersen ray first makes its appearance. At about 15.1 Mc (at the top of the second column) it shows two component pulses, the ordinary and the extraordinary modes. At about 15.3 Mc (near the top of the third column) similar slight separation of the O and X modes in the low-angle ray can be seen. Following the progression upward in the fourth column, as the low-angle and high-angle rays begin to overlap (just above 15.4 Mc) the pulse structure becomes complex; at 15.475 Mc the ordinary rays have combined and at 15.55 Mc only the extraordinary ray pulses are left. These have combined at about 15.625 Mc and have disappeared at 15.7 Mc.

## THE NATIONAL BUREAU OF STANDARDS

The scope of activities of the National Bureau of Standards at its major laboratories in Washington, D.C., and Boulder, Colorado, is suggested in the following listing of the divisions and sections engaged in technical work. In addition, each section carries out specialized research, development, and engineering in the field indicated by the title. A brief description of the activities, and of the resultant publications, appears on the inside of the front cover.

### WASHINGTON, D.C.

Electricity and Electronics. Resistance and Reactance. Electron Devices. Electrical Instruments. Magnetic Measurements. Dielectrics. Engineering Electronics. Electronic Instrumentation. Electrochemistry.

Optics and Metrology. Photometry and Colorimetry. Photographic Technology. Length. Engineering Metrology.

Heat, Temperature Physics. Thermodynamics. Cryogenic Physics. Rheology. Molecular Kinetics. Free-Radiation Research.

Atomic and Radiation Physics. Spectroscopy. Radiometry. Mass Spectrometry. Solid State Physics. Electron Physics. Atomic Physics. Neutron Physics. Radiation Theory. Radioactivity. X-ray. High Energy Radiation. Nuclear Instrumentation. Radiological Equipment.

Chemistry. Organic Coatings. Surface Chemistry. Organic Chemistry. Analytical Chemistry. Inorganic Chemistry. Electrodeposition. Molecular Structure and Properties of Gases. Physical Chemistry. Thermodynamics. Spectrochemistry. Pure Substances.
